Epipolar Lines in Converging Cameras

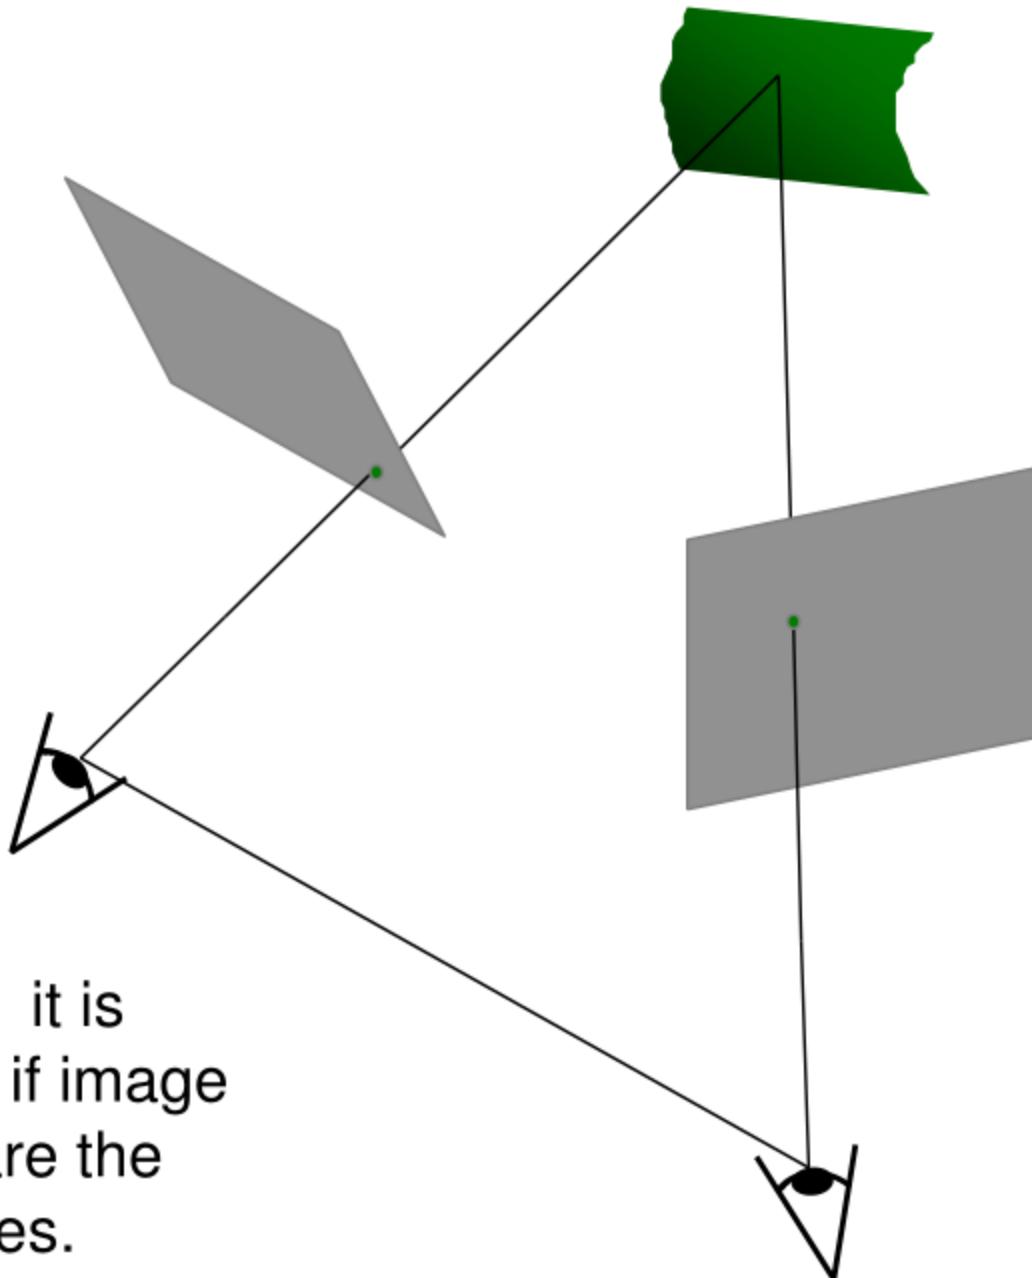

Epipolar lines all intersect at epipoles.

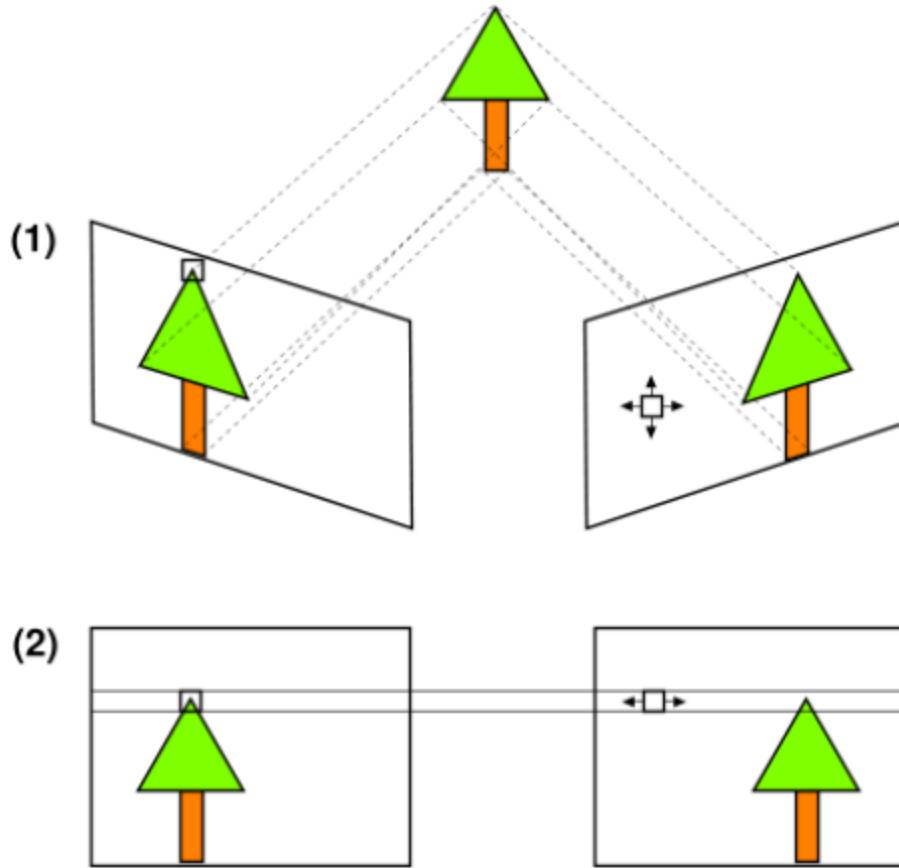

Stereo image rectification

In practice, it is convenient if image scanlines are the epipolar lines.

Image Rectification

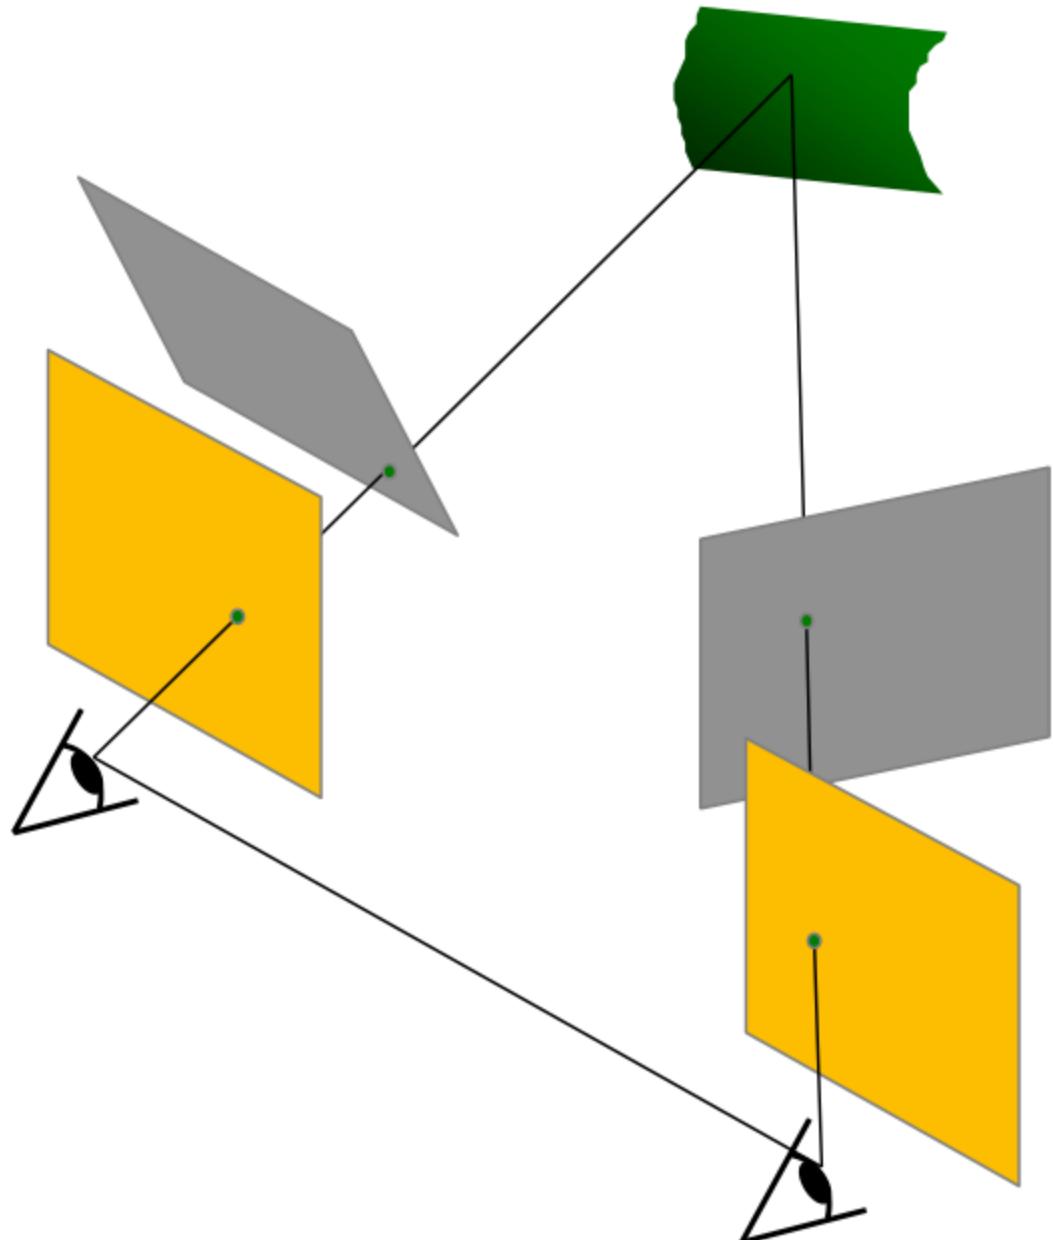

If the two cameras are aligned to be coplanar, the search is simplified to one dimension - a horizontal line parallel to the baseline between the cameras

http://en.wikipedia.org/wiki/Image_rectification

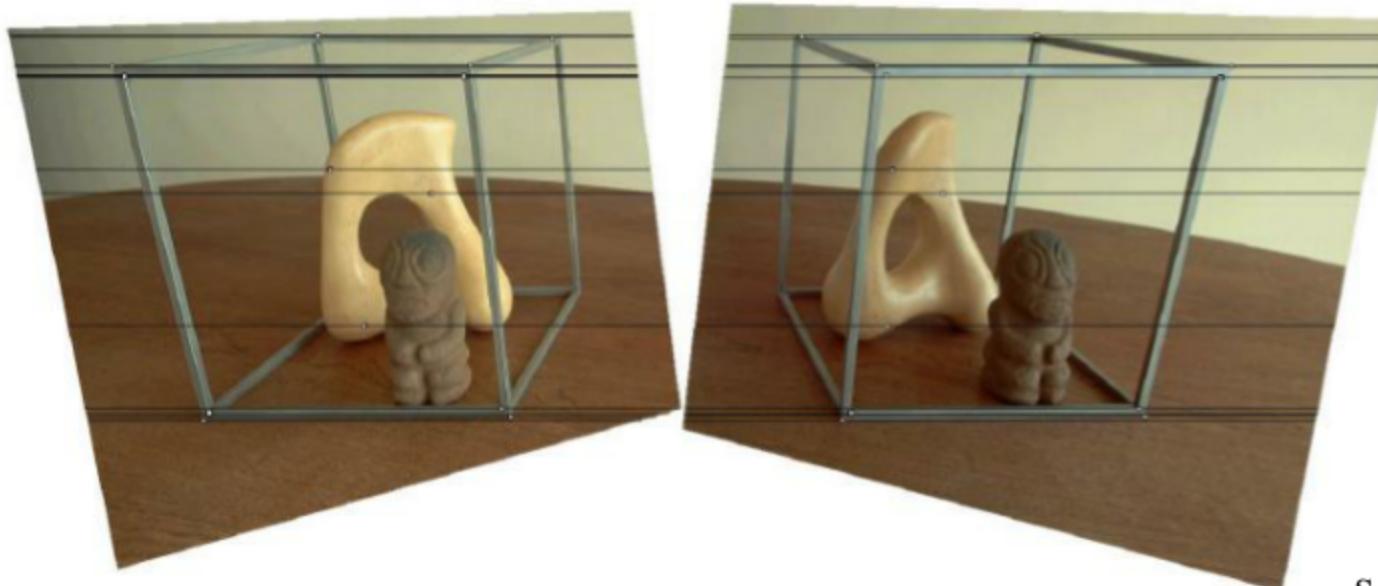

Stereo image rectification

- Image Reprojection
 - reproject image planes onto common plane parallel to line between optical centers
 - a homography (3×3 transform) applied to both input images
 - pixel motion is horizontal after this transformation
 - C. Loop and Z. Zhang. [Computing Rectifying Homographies for Stereo Vision](#). IEEE Conf. Computer Vision and Pattern Recognition, 1999.

Stereo image rectification:

Source: Alyosha Efros

Image Rectification

- Common Image Plane
- Parallel Epipolar Lines
- Search Correspondences on scan line
- Epipoles $\rightarrow \infty$

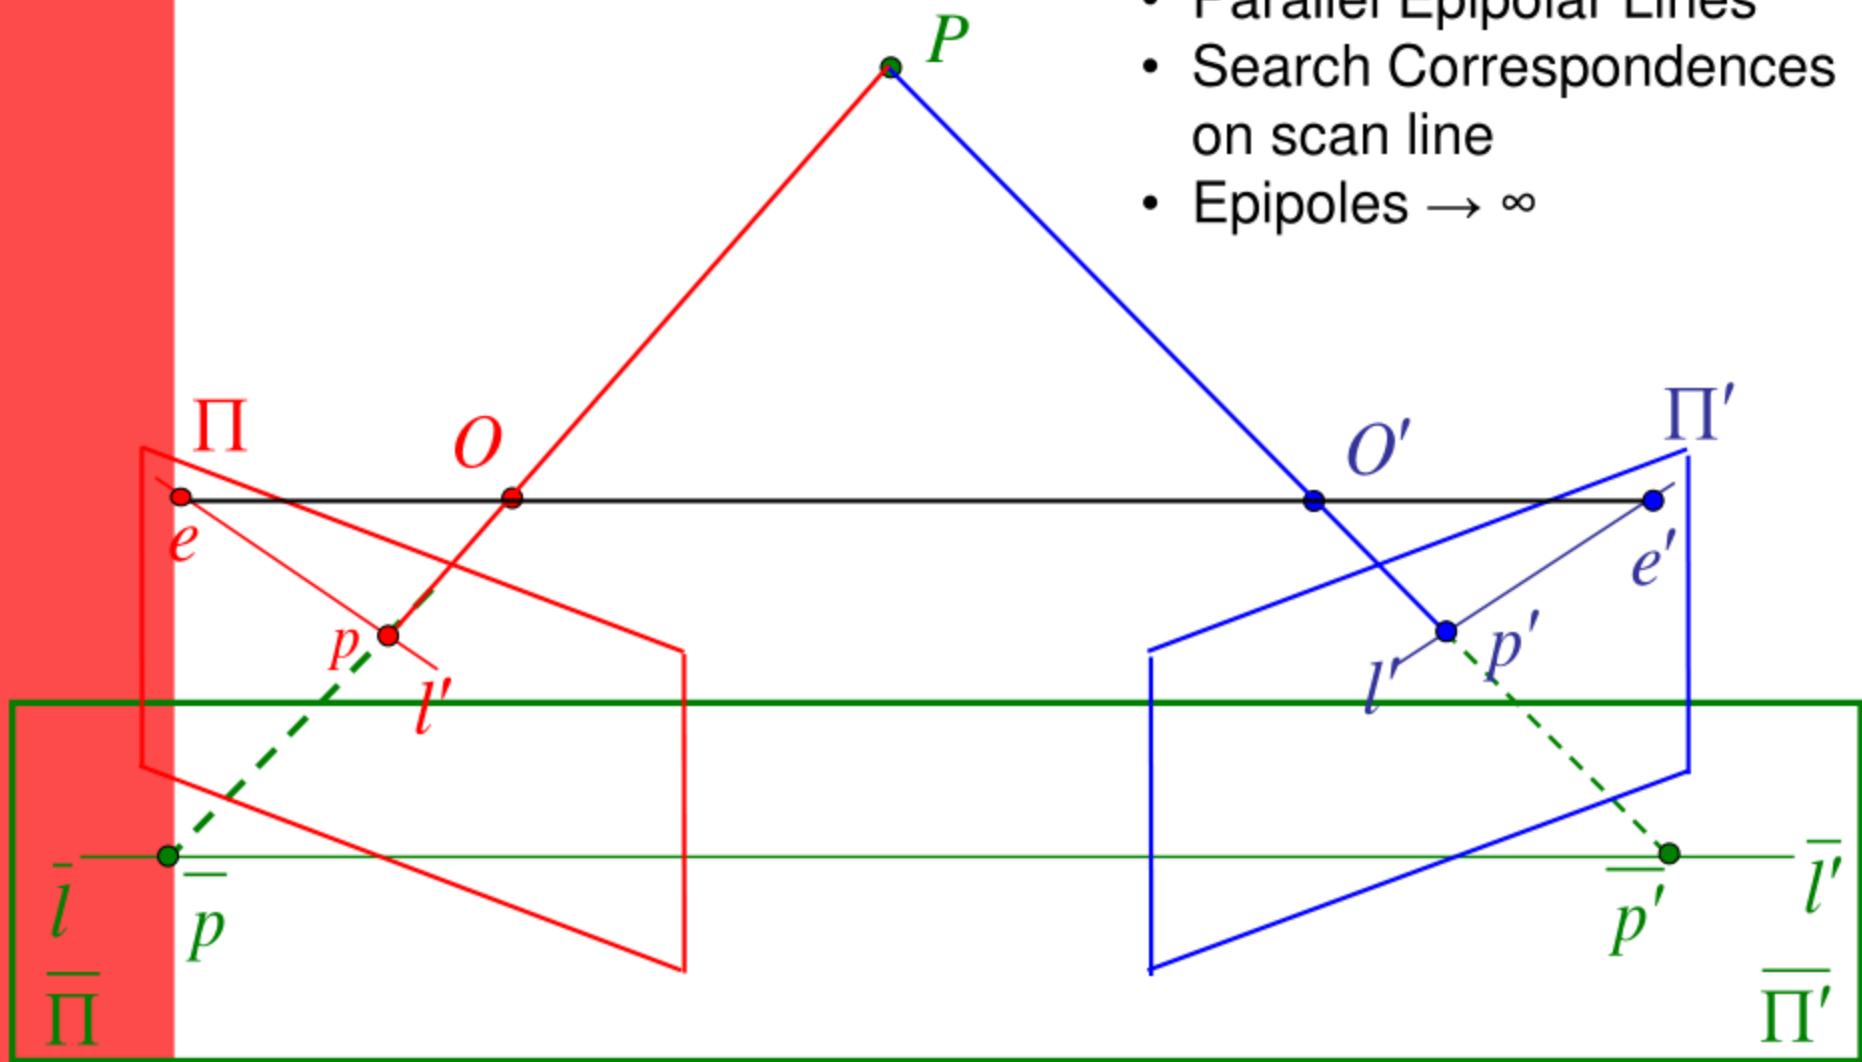

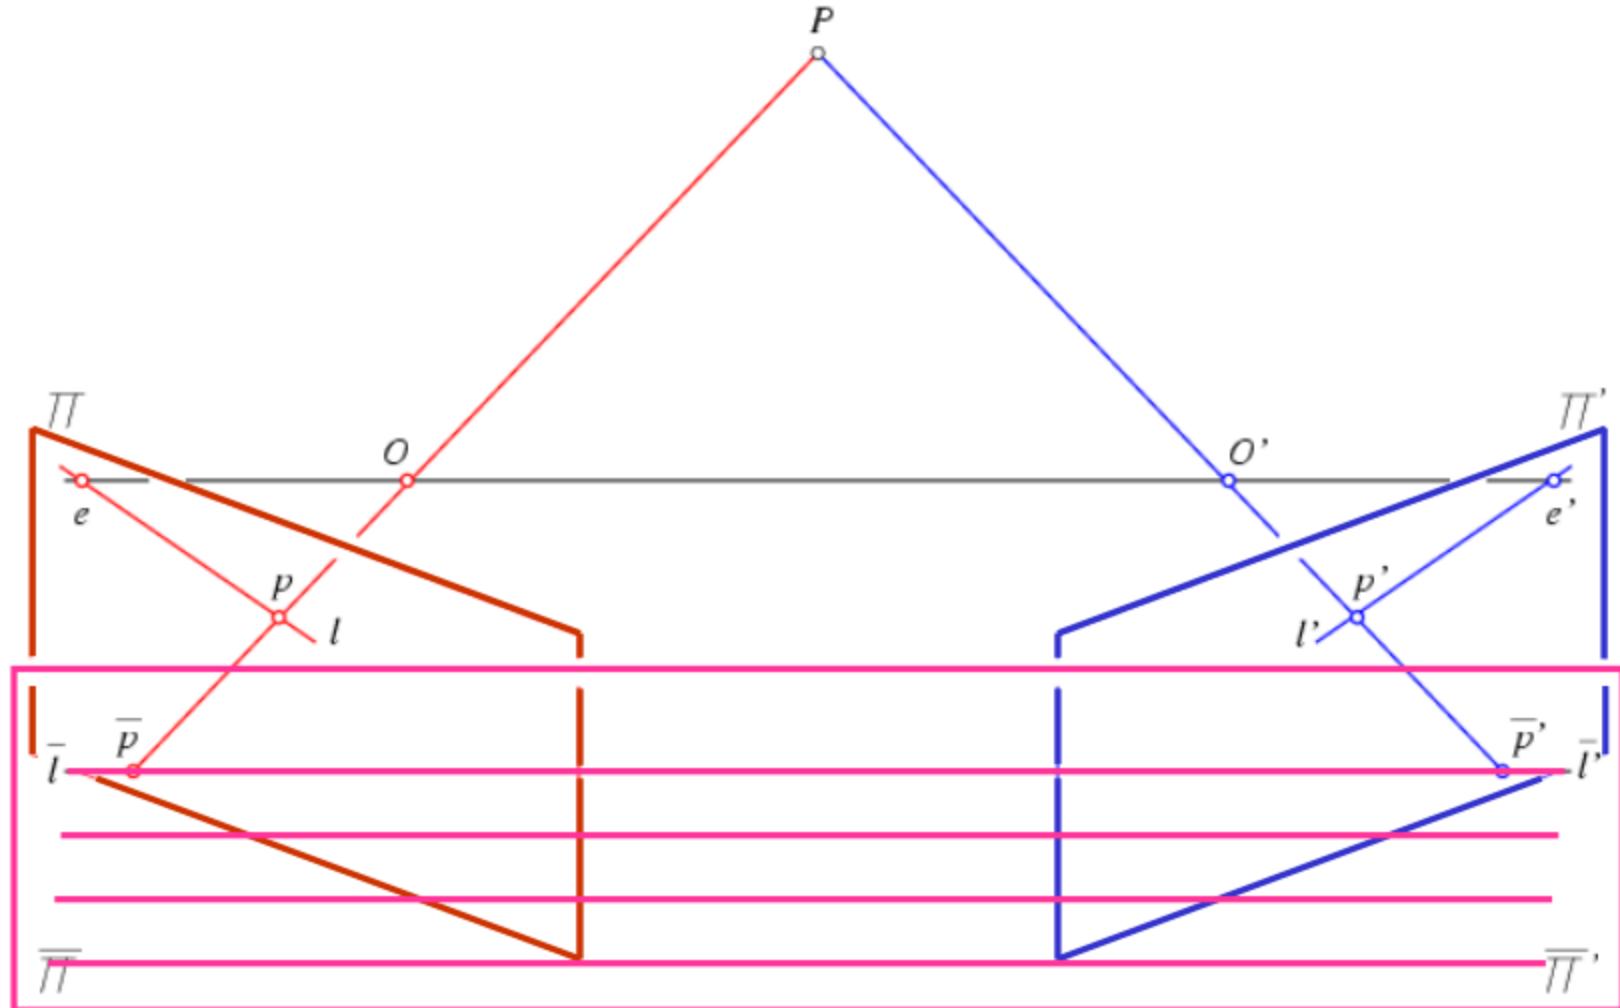

Image Rectification

All epipolar lines are parallel in the rectified image plane.

Image Rectification

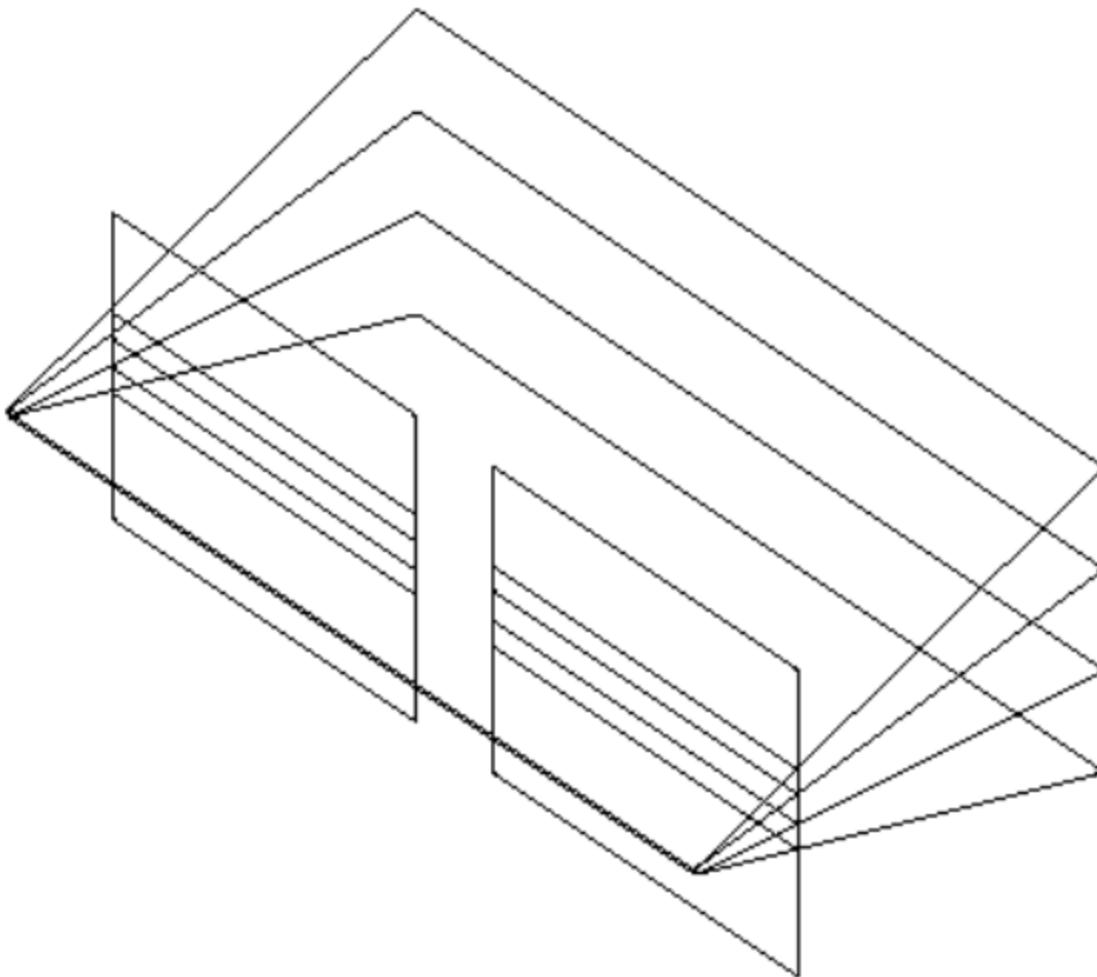

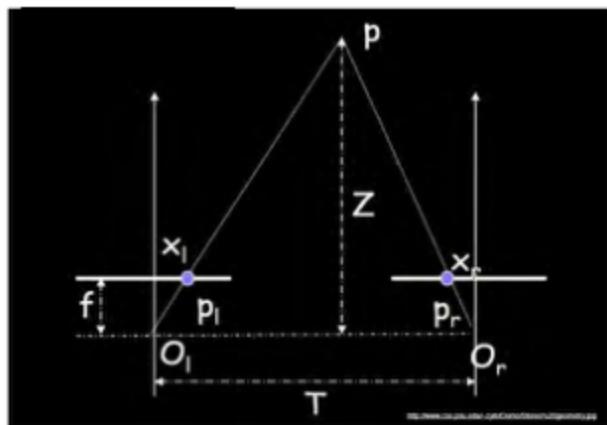

Figure 7.15: Standard stereo setup

Essential matrix example: parallel cameras

$$\mathbf{R} =$$

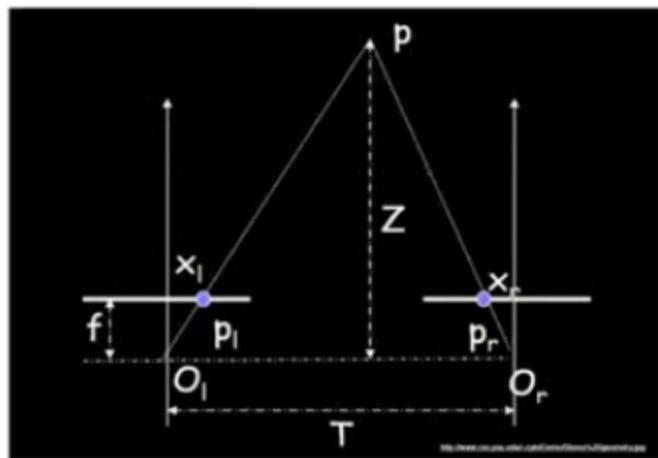

$$\mathbf{T} =$$

$$\mathbf{E} = [\mathbf{T}_x] \mathbf{R} =$$

$$\mathbf{p}'^T \mathbf{E} \mathbf{p} = 0$$

For the parallel cameras,
image of any point must lie on
same horizontal line in each
image plane.

Essential matrix example: parallel cameras

$$\mathbf{R} = \mathbf{I}$$

$$\mathbf{T} = [-d, 0, 0]^T$$

$$\mathbf{E} = [\mathbf{T}_x] \mathbf{R} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & d \\ 0 & -d & 0 \end{pmatrix}$$

$$\mathbf{p}'^T \mathbf{E} \mathbf{p} = 0$$

$$[x' \ y' \ f] \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & d \\ 0 & -d & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ f \end{bmatrix} = 0$$

$$\Leftrightarrow [x' \ y' \ f] \begin{bmatrix} 0 \\ df \\ -dy \end{bmatrix} = 0$$

$$\Leftrightarrow y = y'$$

Example I: compute the fundamental matrix for a parallel camera stereo rig

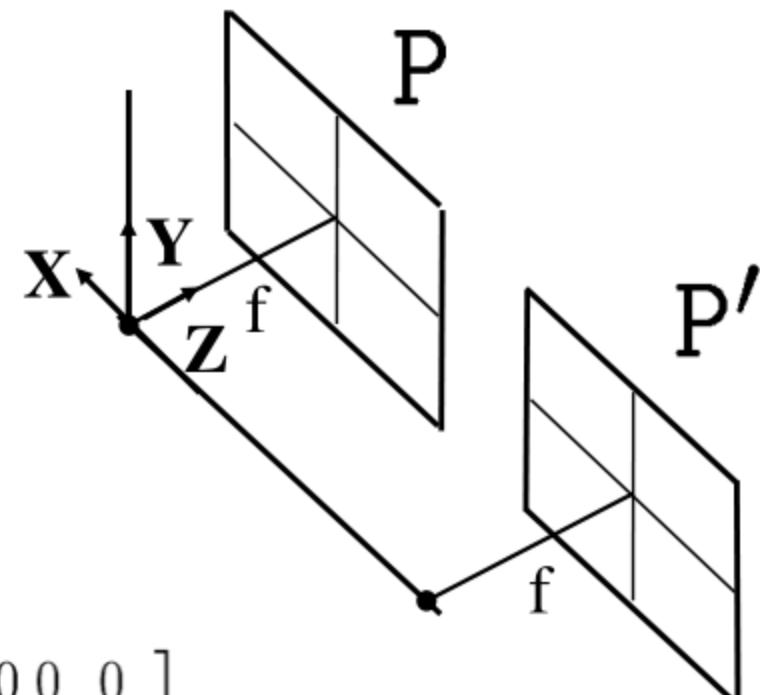

$$P = K[I \mid \mathbf{0}] \quad P' = K'[R \mid t]$$

$$K = K' = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad R = I \quad t = \begin{pmatrix} t_x \\ 0 \\ 0 \end{pmatrix}$$

$$F = K'^{-\top} [t]_x R K^{-1}$$

$$= \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -t_x \\ 0 & t_x & 0 \end{bmatrix} \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix}$$

$$\mathbf{x}'^\top F \mathbf{x} = (x' \ y' \ 1) \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = 0$$

- reduces to $y = y'$, i.e. raster correspondence (horizontal scan-lines)

F is a rank 2 matrix

The epipole e is the null-space vector (kernel) of F (exercise), i.e. $Fe = 0$

In this case

$$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = 0$$

so that

$$e = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}$$

Geometric interpretation ?

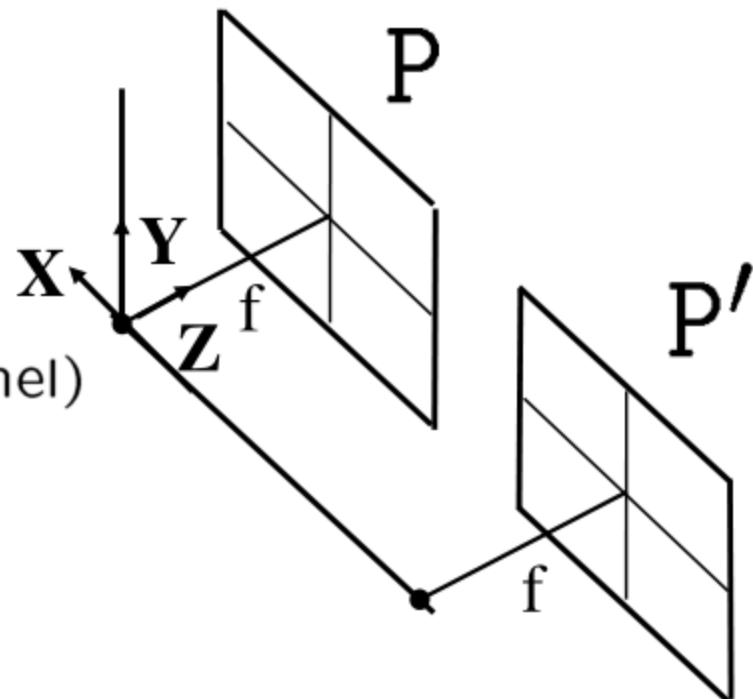

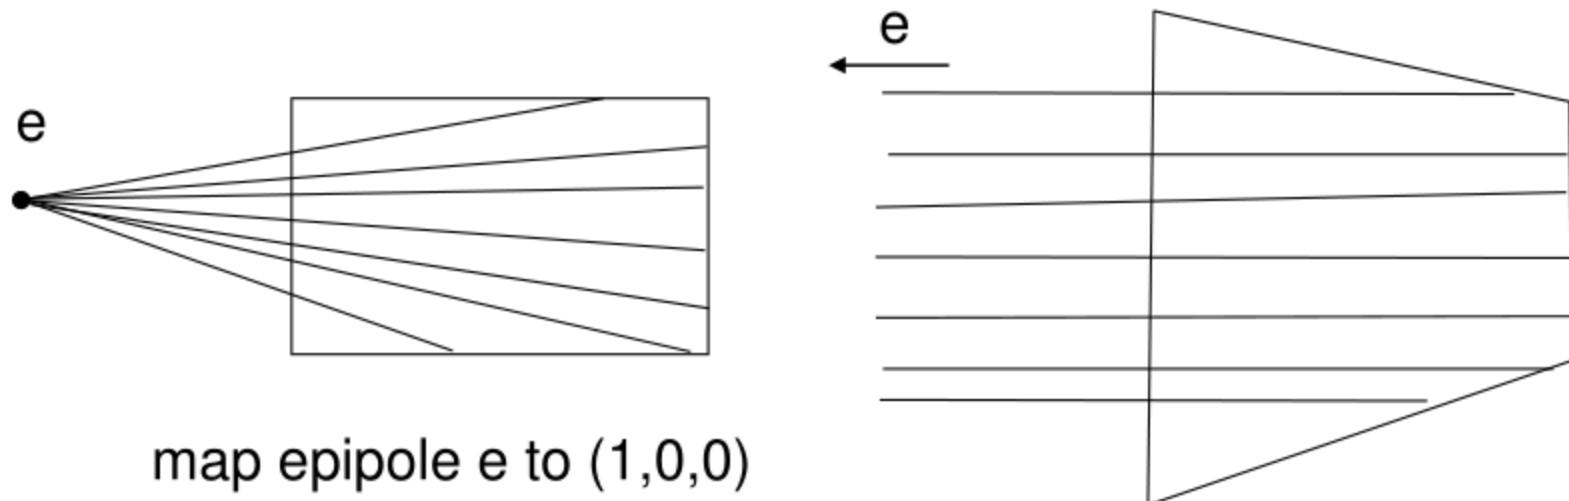

Image pair rectification

Goal: Simplify stereo matching by “warping” the images

Apply projective transformation so that epipolar lines correspond to horizontal scanlines

$$\begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} = H\mathbf{e}$$

map epipole e to $(1,0,0)$

try to minimize image distortion

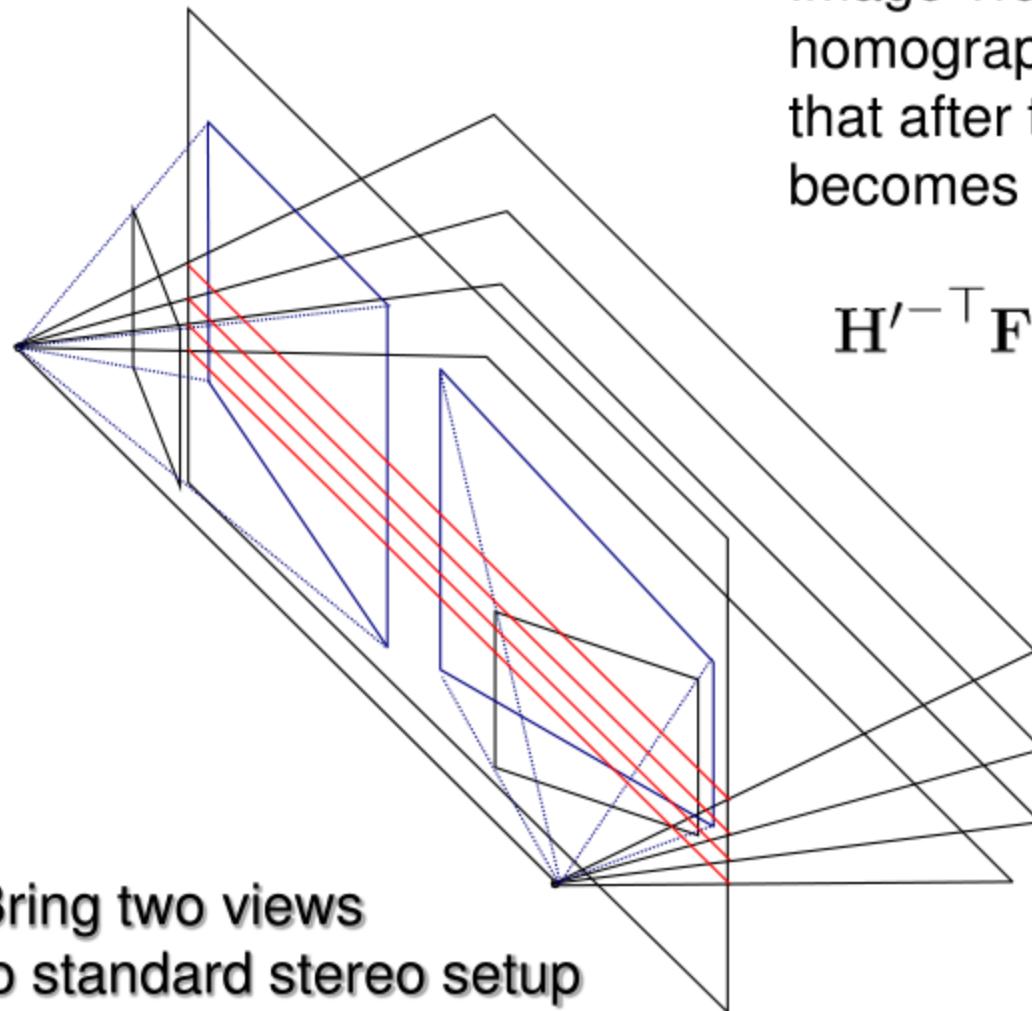

problem when epipole in (or close to) the image

Planar rectification

Image Transformations: Find homographies H' and H so that after transformations, F^n becomes F of parallel cameras:

$$H'^{-\top} F H^{-1} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$$

Bring two views
to standard stereo setup

(moves epipole to ∞)
(not possible when in/close to image)

Algorithm Rectification

Following Trucco & Verri book pp. 159

- known T and R between cameras
- Rotate left camera so that epipole e_l goes to infinity along horizontal axis
- Apply same rotation to right camera to recover geometry
- Rotate right camera by R^{-1}
- Adjust scale

The algorithm consists of four steps:

- Rotate the left camera so that the epipole goes to infinity along the horizontal axis.
- Apply the same rotation to the right camera to recover the original geometry.
- Rotate the right camera by R .
- Adjust the scale in both camera reference frames.

To carry out this method, we construct a triple of mutually orthogonal unit vectors \mathbf{e}_1 , \mathbf{e}_2 , and \mathbf{e}_3 . Since the problem is underconstrained, we are going to make an arbitrary choice. The first vector, \mathbf{e}_1 , is given by the epipole; since the image center is in the origin, \mathbf{e}_1 coincides with the direction of translation, or

$$\mathbf{e}_1 = \frac{\mathbf{T}}{\|\mathbf{T}\|}.$$

The only constraint we have on the second vector, \mathbf{e}_2 , is that it must be orthogonal to \mathbf{e}_1 . To this purpose, we compute and normalize the cross product of \mathbf{e}_1 with the direction vector of the optical axis, to obtain

$$\mathbf{e}_2 = \frac{1}{\sqrt{T_x^2 + T_y^2}} [-T_y, T_x, 0]^\top.$$

The third unit vector is unambiguously determined as

$$\mathbf{e}_3 = \mathbf{e}_1 \times \mathbf{e}_2.$$

It is easy to check that the orthogonal matrix defined as

$$R_{rect} = \begin{pmatrix} \mathbf{e}_1^\top \\ \mathbf{e}_2^\top \\ \mathbf{e}_3^\top \end{pmatrix} \quad (7.22)$$

rotates the left camera about the projection center in such a way that the epipolar lines become parallel to the horizontal axis. This implements the first step of the algorithm. Since the remaining steps are straightforward, we proceed to give the customary algorithm:

Algorithm RECTIFICATION

The input is formed by the intrinsic and extrinsic parameters of a stereo system and a set of points in each camera to be rectified (which could be the whole images). In addition, Assumptions 1 and 2 above hold.

1. Build the matrix R_{rect} as in (7.22);
2. Set $R_l = R_{rect}$ and $R_r = RR_{rect}$;
3. For each left-camera point, $\mathbf{p}_l = [x, y, f]^\top$ compute

$$R_l \mathbf{p}_l = [x', y', z']$$

and the coordinates of the corresponding rectified point, \mathbf{p}'_l , as

$$\mathbf{p}'_l = \frac{f}{z'} [x', y', z'].$$

4. Repeat the previous step for the right camera using R_r and \mathbf{p}_r .

The output is the pair of transformations to be applied to the two cameras in order to rectify the two input point sets, as well as the rectified sets of points.

Additional Materials: Forward Translating Cameras

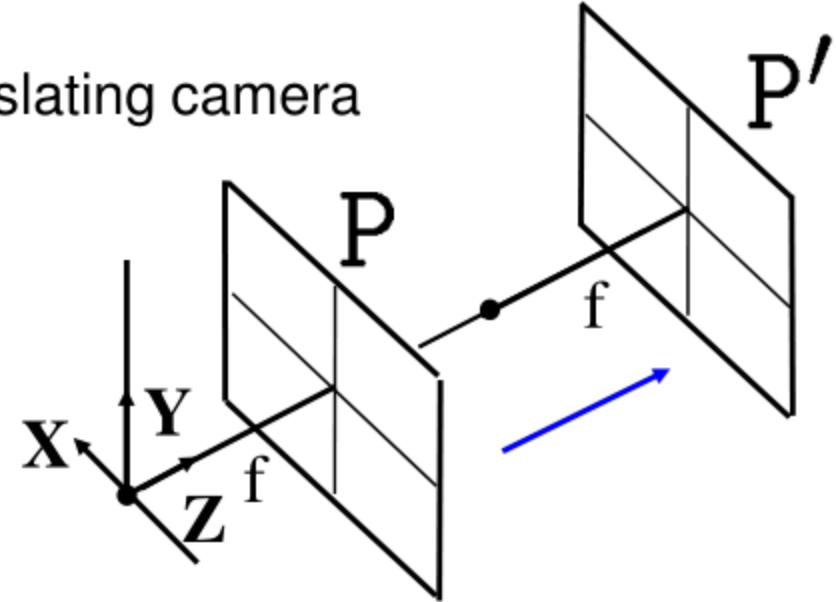

Example II: compute F for a forward translating camera

$$P = K[I \mid \mathbf{0}] \quad P' = K'[R \mid t]$$

$$K = K' = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad R = I \quad t = \begin{pmatrix} 0 \\ 0 \\ t_z \end{pmatrix}$$

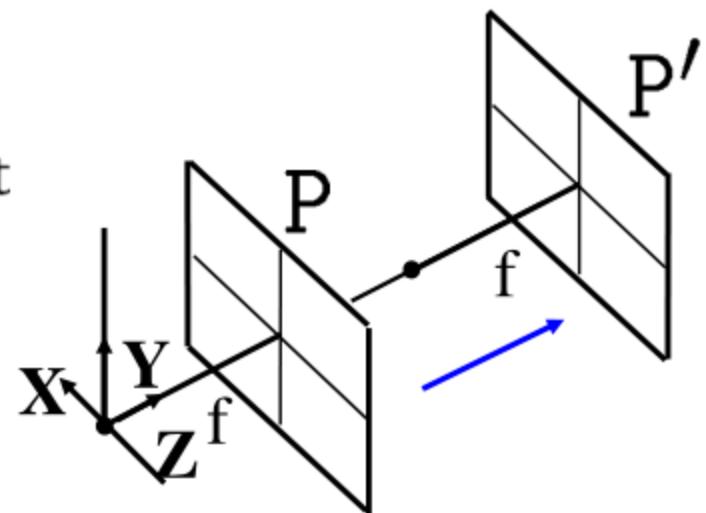

$$F = K'^{-\top} [t] \times R K^{-1}$$

$$= \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 0 & -t_z & 0 \\ t_z & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} 1/f & 0 & 0 \\ 0 & 1/f & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$= \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

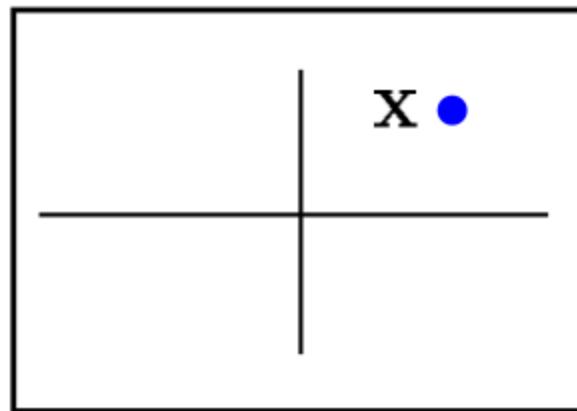

From $\mathbf{l}' = \mathbf{F}\mathbf{x}$ the epipolar line for the point $\mathbf{x} = (x, y, 1)^\top$ is

$$\mathbf{l}' = \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{pmatrix} x \\ y \\ 1 \end{pmatrix} = \begin{pmatrix} -y \\ x \\ 0 \end{pmatrix}$$

The points $(x, y, 1)^\top$ and $(0, 0, 1)^\top$ lie on this line

first image

second image
